# Software modules

## Overview

The software stack on OWL is organized with loadable modules. Software packages are automatically generated based on [SPACK](#) and [LMOD](#).

## Working with modules

Tab completion of module names works currently with bash, but not with csh/tcsh.

```
# list available modules
module avail

# search for a certain module
module spider [modulename]

# load a module (use full path if multiple versions exist)
module load [modulename]

# list loaded modules
module list

# unload modules
module rm [modulename]

# unload all currently loaded modules
module purge
```

Some of the modules depend on other modules, e.g., on a certain compiler module. These modules will only show up in the avail list, if the dependency was pre-loaded. However, you can find all versions of a module using module spider, e.g., *module spider netcdf-c*.
